Chapter 5

# **Pipelined Computations**

Pipelined Computations

Problem divided into a series of tasks that have to be completed one after the other (the basis of sequential programming).

Each task executed by a separate process or processor.

Example

Add all the elements of array **a** to an accumulating sum:

```
for (i = 0; i < n; i++)
  sum = sum + a[i];
```
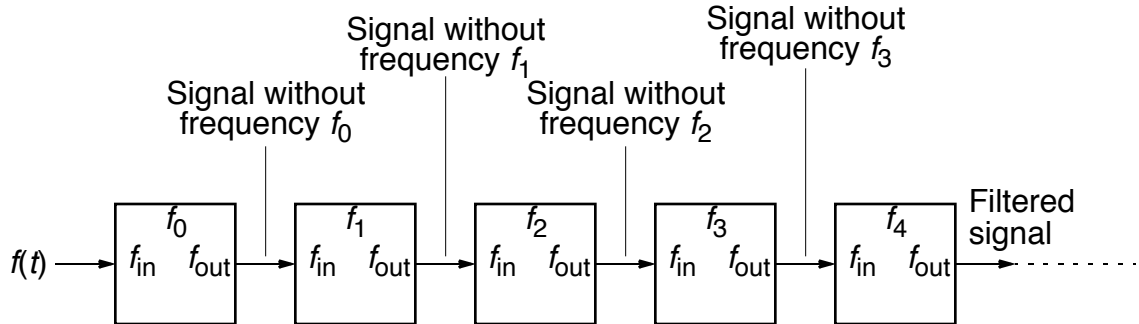

The loop could be "unfolded" to yield

```
sum = sum + a[0];
sum = sum + a[1];
sum = sum + a[2];
sum = sum + a[3];
sum = sum + a[4];
    .
```

Pipeline for an unfolded loop

Another Example

Frequency filter - Objective to remove specific frequencies (f_0, f_1, f_2, f_3, etc.) from a digitized signal, $f(t)$. Signal enters pipeline from left:

Where pipelining can be used to good effect

Assuming problem can be divided into a series of sequential tasks, pipelined approach can provide increased execution speed under the following three types of computations:

1. If more than one instance of the complete problem is to be executed

2. If a series of data items must be processed, each requiring multiple operations

3. If information to start the next process can be passed forward before the process has completed all its internal operations

"Type 1" Pipeline Space-Time Diagram
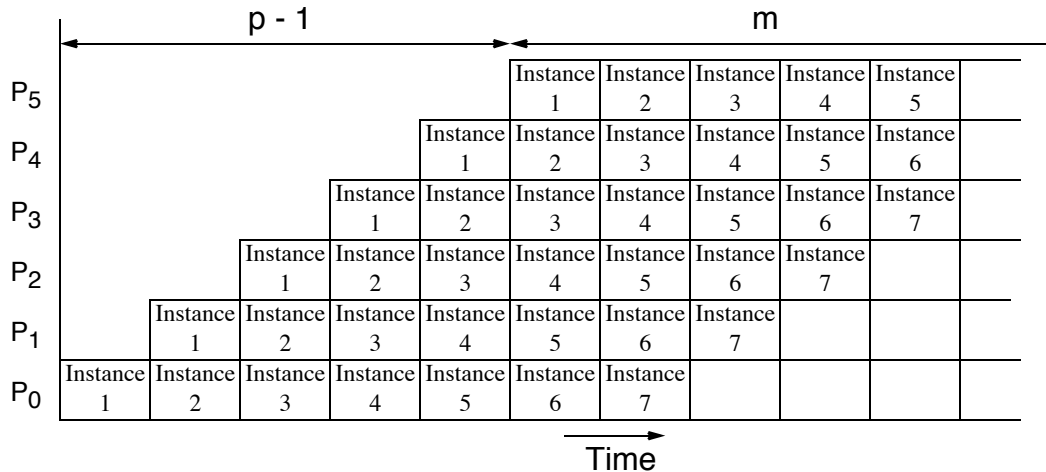

Execution time = m + p - 1 cycles for a p-stage pipeline and m instances.

Pipeline processing where information passes to next stage before end of process.

If the number of stages is larger than the number of processors in any pipeline, a group of stages can be assigned to each processor:
Computing Platform for Pipelined Applications

Multiprocessor system with a line configuration.

Strictly speaking pipeline may not be the best structure for a cluster - however a cluster with switched direct connections, as most have, can support simultaneous message passing.

Example Pipelined Solutions

(Examples of each type of computation)

Pipeline Program Examples

Adding Numbers

$$\sum_1 i \qquad \sum_1^2 i \qquad \sum_1^3 i \qquad \sum_1^4 i \qquad \sum_1^5 i$$

$P_0 \rightarrow P_1 \rightarrow P_2 \rightarrow P_3 \rightarrow P_4 \rightarrow$
Type 1 pipeline computation

Basic code for process P_i :

```
recv(&accumulation, P_{-1});
accumulation = accumulation + number;
send(&accumulation, P_{+1});
```

except for the first process, P_0, which is

```
send(&number, P_1);
```

and the last process, P_{n-1}, which is

```
recv(&number, P_{n-2});

accumulation = accumulation + number;
```
SPMD program

```
if (process > 0) {
  recv(&accumulation, P_{i-1});
  accumulation = accumulation + number;
}
if (process < n-1) send(&accumulation, P_{i+1});
```

The final result is in the last process.
Instead of addition, other arithmetic operations could be done.

Pipelined addition numbers with a master process and ring configuration

Master process   Slaves

$d_{n-1}\ldots d_2 d_1 d_0$ → P_0 → P_1 → P_2 - - - → P_{n-1}

Sum

Sorting Numbers

A parallel version of *insertion sort*.

$x_{n-1} \ldots x_1 x_0$

P_0

Smaller numbers

P_1

P_2

Compare

x_{max}

Largest number

Next largest number
Type 2 pipeline computation

The basic algorithm for process P_i is

```
recv(&number, P_{i-1});
if (number > x) {
  send(&x, P_{i+1});
  x = number;
} else send(&number, P_{i+1});
```

With *n* numbers, how many the *i*th process is to accept is known; it is given by *n* – *i*. How many to pass onward is also known; it is given by *n* – *i* – 1 since one of the numbers received is not passed onward. Hence, a simple loop could be used.

Insertion sort with results returned to the master process using a bidirectional line configuration

Master process

Time
Prime Number Generation

Sieve of Eratosthenes

Series of all integers is generated from 2. First number, 2, is prime and kept. All multiples of this number are deleted as they cannot be prime. Process repeated with each remaining number. The algorithm removes nonprimes, leaving only primes.

Pipeline for Prime Number Generation

number

3rd prime
number

Type 2 pipeline computation

The code for a process, P_i, could be based upon

```
recv(&x, P_{i-1});
/* repeat following for each number */
recv(&number, P_{i-1});
if ((number % x) != 0) send(&number, P_{i+1});
```

Each process will not receive the same amount of numbers and the amount is not known beforehand. Use a "terminator" message, which is sent at the end of the sequence:

```
recv(&x, P_{i-1});
for (i = 0; i < n; i++) {
  recv(&number, P_{i-1});
  if (number == terminator) break;
  if (number % x) != 0) send(&number, P_{i+1});
}
```

Solving a System of Linear Equations

Upper-triangular form

$a_{n-1,0}x_0 + a_{n-1,1}x_1 + a_{n-1,2}x_2 \quad \ldots \quad + a_{n-1,n-1}x_{n-1} \qquad = b_{n-1}$

.

.

$a_{2,0}x_0 + a_{2,1}x_1 + a_{2,2}x_2 \qquad\qquad\qquad\qquad = b_2$

$a_{1,0}x_0 + a_{1,1}x_1 \qquad\qquad\qquad\qquad\qquad = b_1$

$a_{0,0}x_0 \qquad\qquad\qquad\qquad\qquad\qquad = b_0$

where the *a's* and *b's* are constants and the *x*'s are unknowns to be found.

Back Substitution

First, the unknown x_0 is found from the last equation; i.e.,

$$x_0 = \frac{b_0}{a_{0,0}}$$

Value obtained for x_0 substituted into next equation to obtain x_1; i.e.,

$$x_1 = \frac{b_1 - a_{1,0}x_0}{a_{1,1}}$$

Values obtained for x_1 and x_0 substituted into next equation to obtain x_2:

$$x_2 = \frac{b_2 - a_{2,0}x_0 - a_{2,1}x_1}{a_{2,2}}$$

and so on until all the unknowns are found.

Pipeline Solution

First pipeline stage computes x_0 and passes x_0 onto the second

stage, which computes x_1 from x_0 and passes both x_0 and x_1 onto

the next stage, which computes x_2 from x_0 and x_1, and so on.

Type 3 pipeline computation

The ith process ($0 < i < n$) receives the values x_0, x_1, x_2, …, x_{i-1} and computes x_i from the equation:

$$x_i = \frac{b_i - \displaystyle\sum_{j=0}^{i-1} a_{i,j} x_j}{a_{i,i}}$$

Sequential Code

Given the constants $a_{i,j}$ and b_k stored in arrays **a[][]** and **b[]**,

respectively, and the values for unknowns to be stored in an array,

x[], the sequential code could be

```
x[0] = b[0]/a[0][0]; /* computed separately */
for (i = 1; i < n; i++) {/* for remaining
unknowns */
   sum = 0;
   for (j = 0; j < i; j++
     sum = sum + a[i][j]*x[j];
   x[i] = (b[i] – sum)/a[i][i];
   }
```

Parallel Code

Pseudocode of process P_i ($1 < i < n$) of could be

```
for (j = 0; j < i; j++) {
  recv(&x[j], P_{i-1});
  send(&x[j], P_{i+1});
}
sum = 0;
for (j = 0; j < i; j++)
  sum = sum + a[i][j]*x[j];
x[i] = (b[i] – sum)/a[i][i];
send(&x[i], P_{i+1});
```

Now additional computations after receiving and resending values.

Pipeline processing using back substitution
